## 1. Additional Experimental Section

General - All starting materials and reagents were commercially available and were used without further purification. ${ }^{1} \mathrm{H}$ NMR spectra (250, 300, 400 and 500 MHz ) and ${ }^{13} \mathrm{C}$ NMR spectra ( $63,75,100$ and 125 MHz ) were measured in deuterated solvents. $J$ values are given in Hertz. NMR assignments were carried out by a combination of 1 D , COSY, and DEPT-135 experiments. FT-IR spectra were recorded as NaCl plates or KBr discs in a PerkinElmer Two FTIR spectrometer with attenuated total reference. $[\alpha]_{\mathrm{D}}^{20}=$ values are given in $10^{-1} \mathrm{deg} \mathrm{cm}^{2} \mathrm{~g}^{-1}$. MilliQ deionized water was used in all the buffers. All procedures involving the use of ion-exchange resins were carried out at room temperature using Milli-Q deionized water. Amberlite IR-120 ( $\mathrm{H}^{+}$) (cation exchanger) was washed alternately with water, NaOH ( $10 \%$ ), water, $\mathrm{HCl}(10 \%)$, and finally water before use. The spectroscopic measurements were made on a Varian Cary 100 UV-Vis spectrophotometer with a 1 cm pathlength cell fitted with a Peltier temperature controller. The purity of the reported compounds was analyzed by HPLC and by NMR. HPLC was performed on either a Bio-Rad Aminex ion exclusion HPX-87H organic acids column ( $300 \mathrm{~mm} \times 16 \mathrm{~mm}$ ), eluting with 100 mM aqueous formic acid at a flow rate of $0.6 \mathrm{~mL} \mathrm{~min}^{-1}$ or a Phenomenex Luna $5 \mu \mathrm{M}$ C18 column ( $250 \mathrm{~mm} \times 4.6 \mathrm{~mm}$ ), eluting with a gradient of acetonitrile/water [from (5:95) to (30:70)] at a flow rate of $1 \mathrm{~mL} \mathrm{~min}^{-1}$. All tested compounds have a purity $\geq 95 \%$.

### 1.1 Synthesis of Compounds 9-14

The synthesis of compounds $\mathbf{9 - 1 4}$ was performed as outlined in Scheme S1.

Scheme S1 Synthesis of compounds 9-14. Reagents and conditions. (a) 1. $\mathrm{SOCl}_{2}, \mathrm{CHCl}_{3}, \Delta$. 2. dimethyl 5aminoisophathalate, $\mathrm{CH}_{2} \mathrm{Cl}_{2}, \mathrm{Et}_{3} \mathrm{~N}, \mathrm{RT}$. (b) dimethyl 5-aminoisophathalate, HATU, DIPEA, $\mathrm{CH}_{2} \mathrm{Cl}_{2}, \mathrm{RT}$. (c) 1. LiOH, THF, RT. 2. HCl. (d) cis-1,2-cyclohexanedicarboxylic anhydride, DMAP, $\mathrm{Et}_{3} \mathrm{~N}$, THF, RT. (e) trans-1,2cyclohexanedicarboxylic anhydride, DMAP, Et ${ }_{3} \mathrm{~N}$, DMF, RT. (f) methyl glycylglycinate, HATU, DIPEA, $\mathrm{CH}_{2} \mathrm{Cl}_{2}, \mathrm{RT}$. (e) 1. LiOH, THF, RT. 2. Dowex 50W X8-400 $\left(\mathrm{NH}_{4}{ }^{+}\right.$form $)$.

Dimethyl 5-(2-(2-methoxyphenyl)acetamido)isophthalate (43) - A solution of 2methoxyphenyl acetic acid (41) (114 mg, 0.69 mmol$)$ and thionyl chloride $(0.10 \mathrm{~mL}, 1.38 \mathrm{mmol})$ in chloroform ( 2.8 mL ) was heated under reflux for 2 h . After cooling to room temperature, solvents were removed under reduced pressure. The resulting residue was dissolved in dry dichloromethane ( 2 mL ) and it was added via canula to a suspension of dimethyl 5aminoisophathalate ( $148 \mathrm{mg}, 0.69 \mathrm{mmol}$ ) and triethylamine $(0.14 \mathrm{~mL}, 1.00 \mathrm{mmol})$ in dry dichloromethane ( 3.45 mL ). After 3 h , the reaction mixture was diluted with dichloromethane and aqueous $\mathrm{HCl}(10 \%)$. The aqueous layer was separated and the organic extract was washed successively with saturated sodium bicarbonate and brine. The organic extract was dried (anh. $\mathrm{Na}_{2} \mathrm{SO}_{4}$ ), filtered and concentrated under reduced pressure. The residue obtained was purified by flash chromatography, eluting with (60:40) diethyl acetate/hexane, to afford the amide $\mathbf{4 3}$ ( $240 \mathrm{mg}, 97 \%$ ) as white solid. 1.2 Fragment-based screeing - It was performed following previously described protocol. ${ }^{27}$ The enzyme geometries found in PDB code $2 \mathrm{WKS}^{9 \mathrm{~m}}$ was used. Taking into account that unfolding and refolding studies of DHQ2 have shown that the trimer ${ }^{47}$ is the biological unit of the enzyme, the trimer was used for these studies. The trimer composed by chains A, B and E in 2 WKS was considered.
1.3 Dehydroquinase Assays - The enzyme was purified and assayed as described previously. ${ }^{48}$
1.4 Molecular dynamics simulations - Ligand minimization. Ligand geometries were optimized using a restricted Hartree-Fock (RHF) method and a $6-31 \mathrm{G}(\mathrm{d}, \mathrm{p})$ basis set, as implemented in the ab initio program Gaussian 09. ${ }^{49}$ The resulting wavefunctions were used to calculate electrostatic potential-derived (ESP) charges employing the restrained electrostatic potential (RESP) ${ }^{50}$ methodology, as implemented in the assisted model building with energy refinement (AMBER) suite of programs. The missing bonded and non-bonded parameters were assigned, by analogy or through interpolation from those already present in the AMBER database (GAFF). ${ }^{49,51}$

Generation and minimization of the DHQ2-ligand complexes. Simulations were carried out using the enzyme geometries found in PDB code $2 \mathrm{WKS}^{9 \mathrm{~m}}$ (chains A, B and E). ${ }^{9 \mathrm{~m}}$ The trimer composed by chains A, B and E in 2 WKS was considered. Computation of the protonation state of titratable groups at pH 7.0 was carried out using the $\mathrm{H}++$ Web server. ${ }^{52} \delta$ and/or $\varepsilon$ protonation was manually corrected for His102 (dual) of the active site due to mechanistic considerations. Addition of hydrogen and molecular mechanics parameters from the ff $14 \mathrm{SB}^{53}$ and GAFF force fields, respectively, were assigned to the protein and the ligands using the LEaP module of AMBER Tools $14 .{ }^{54}$ ${ }^{55}$ The protein was immersed in a truncated octahedron of $\sim 19000$ TIP3P water molecules and neutralized by addition of sodium ions. ${ }^{50} 56{ }^{57}$ The system was minimized in three stages: (a) minimization of the solvent and ions ( 5000 steps, first half using steepest descent and the rest using conjugate gradient); (b) minimization of the side chains, waters and ions (5000 steps, first half using steepest descent and the rest using conjugate gradient); (c) final minimization of the whole system (5000 steps, first half using steepest descent and the rest using conjugate gradient). A positional restraint force of $50 \mathrm{kcal} \mathrm{mol}^{-1} \AA^{-2}$ was applied to the whole protein and $\alpha$ carbons during the first two stages (a-b), respectively.

Simulations. MD simulations were performed using the pmemd.cuda_SPFP ${ }^{58}{ }^{59}$ module from the AMBER 14 suite of programs. Periodic boundary conditions were applied and electrostatic interactions were treated using the smooth particle mesh Ewald method (PME) ${ }^{61}$ with a grid spacing of $1 \AA$. The cutoff distance for the non-bonded interactions was $9 \AA$. The SHAKE algorithm ${ }^{62}$ was applied to all bonds containing hydrogen, using a tolerance of $10^{-5} \AA$ and an integration step of 2.0 fs . Minimization was carried out in three steps, starting with the octahedron water hydrogens, followed by solvent molecules and sodium counterions and finally the entire system. The minimized system was then heated at 300 K at 1 atm by increasing the temperature from 0 K to 300 K over 100 ps and by keeping the system at 300 K another 100 ps . A positional restraint force of $50 \mathrm{kcal} \mathrm{mol}^{-1} \AA^{-2}$ was applied to all $\alpha$
carbons during the heating stage. Finally, an equilibration of the system at constant volume ( 200 ps with positional restraints of $5 \mathrm{kcal} \mathrm{mol}^{-1} \AA^{-2}$ to $\alpha$ alpha carbons) and constant pressure (another 100 ps with positional restraints of $5 \mathrm{kcal} \mathrm{mol}^{-1} \AA^{-2}$ to $\alpha$ alpha carbons) were performed. The positional restraints were gradually reduced from 5 to $1 \mathrm{~mol}^{-1} \AA^{-2}$ ( 5 steps, 100 ps each), and the resulting systems were allowed to equilibrate further ( 100 ps ). Unrestrained MD simulations were carried out for 100 ns . System coordinates were collected every 10 ps for further analysis. Figures depicting structures were prepared using PYMOL. ${ }^{63}$ The cpptraj module in AMBER 14 was used to analyze the trajectories and to calculate the root-mean-square deviations (RMSD) of the protein during the simulation. ${ }^{64}$

Figure S1. Detailed view of the Hp-DHQ2 Michaelis complex obtained by MD simulation studies. The C 1 binding pocket is highlighted (cyan). Note how the natural substrate ( $\mathbf{1}$, yellow) is anchored in the C 1 binding pocket by six hydrogen bonds with residues Thr104, Leu103, His102, and Asn76. The essential His102 acts as a proton donor in the final step of the reaction, i.e. the acid-catalyzed elimination of the C 1 hydroxyl group. Relevant residues are shown and labeled. Hydrogen-bonding and lipophilic interactions are indicated as red and grey dashed lines, respectively.

Figure S2. Selected view of the predicted binding mode of ligands: (A) $\mathbf{1 0}$ (yellow), (B) $\mathbf{1 1}$ (green), (C) $\mathbf{8}$ (pink), (D) $\mathbf{1 2}$ (yellow), and (E) $\mathbf{1 3}$ (cyan) in the $H p-\mathrm{DHQ} 2$ active site. Note how the less potent inhibitors, i.e. compounds $\mathbf{8}$ and 12, do not interact with the C 1 binding pocket, which is key for substrate recognition. Relevant side chain residues are shown and labeled. The neighboring chain (blue) close to the active site chain residues (*) are shown and labeled. Hydrogenbonding and lipophilic interactions are indicated as red and grey dashed lines, respectively.
